Bridge Analytics and KPI Plan

Measurement plan | Version 1.0 | 2 November 2026

Purpose

This plan defines a small measurement system for the Bridge pilot. The goal is to understand whether both sides complete the marketplace loop, where they get stuck, and whether task quality and response behavior are adequate. Numeric targets are intentionally blank because no baseline, launch segment, or business targets were supplied.

Measurement principles

- Measure completed actions, not just page views or signups.
- Define numerator, denominator, eligibility, and time window before reporting a rate.
- Separate observed data from estimates and qualitative feedback.
- Collect only events needed for product decisions; avoid logging message content or secrets.
- Segment carefully by pilot cohort, task category, and participant side; suppress very small groups when sharing results.
- Every KPI has an owner and a source of truth.

North-star candidate

Qualified task matches per active pilot period could represent completed value on both sides, but "qualified," "match," and the reporting period must be agreed. Until then, use it as a candidate, not an official KPI.

KPI definitions

KPI	Definition	Why it matters	Owner / source
Profile completion	Eligible student profiles with required fields complete ÷ profiles started.	Measures supply onboarding friction.	Product; profile records.
Task publication rate	Task drafts submitted for review that reach the agreed published state ÷ task drafts submitted.	Measures owner setup and task quality process.	Marketplace lead; task state history.
Task-to-qualified-application rate	Published tasks receiving at least one application that meets the agreed relevance rubric ÷ published tasks in cohort.	Tests whether supply matches demand.	Marketplace lead; application + review rubric.
Application conversion	Task detail views by eligible students that lead to an application ÷ eligible detail views.	Identifies discovery/application friction.	Product; privacy-reviewed events.
Owner response time	Median elapsed time from first application to first owner decision per task.	Captures marketplace responsiveness.	Marketplace lead; timestamps.
Decision coverage	Applications with a decision within the defined observation window ÷ eligible applications.	Shows whether applicants receive closure.	Marketplace lead; application records.
Acceptance rate	Applications accepted ÷ applications decided.	Tracks selection outcomes; interpret with task mix.	Product; application state history.
Conversation activation	Accepted relationships with at least one message from each participant within window ÷ accepted relationships eligible for chat.	Measures post-match coordination.	Product; message metadata only.
Repeat intent/behavior	Participants returning for another task/application within period; report sides separately.	Indicates potential retained value.	Product; account and task records.
Support burden	Support requests per active participant and time to resolution.	Assesses operational scalability.	Support owner; issue log.
Trust/safety incident rate	Reports by category per active participant/task; pair with resolution time and recurrence.	Monitors risk; avoid optimizing for low reporting alone.	Trust owner; restricted incident log.

Event plan

Proposed event names: **profile_started**, **profile_completed**, **task_draft_created**, **task_published**, **task_viewed**, **application_submitted**, **application_decided**, **conversation_opened**, **message_sent** (metadata only), **support_request_opened**, and **report_received** (restricted system). Each event should include event ID, timestamp, actor ID pseudonym, cohort, relevant object ID, and source screen. Do not include free-text proposal/message bodies, credentials, or direct identifiers in general analytics events.

Funnel definitions

Student funnel

Invited/reached to profile started to profile completed to task viewed to application submitted to decision received to accepted to conversation activated to repeat participation.

Task-owner funnel

Reached to interested to account activated to task draft to task published to qualified applicant received to decision recorded to conversation activated to repeat task intent/posting.

Report counts at every stage and conversion between adjacent stages. Define what qualifies as "reached," "active," "qualified," and "repeat" before comparing cohorts.

Pilot dashboard

Weekly view should include: current cohort size by side; published tasks; tasks with/without applications; applications submitted and decided; owner response time; conversation activation; repeat behavior; support volume; active trust issues by priority; and known product blockers. Include date range, cohort definition, data freshness, and metric owner.

Baselines and targets

Measure	Baseline	Pilot target	Decision owner
Profile completion	To measure	To set after baseline	Product owner
Tasks receiving a qualified application	To measure	To set after segment selection	Marketplace lead
Owner response time	To measure	To agree for pilot	Marketplace lead
Application decision coverage	To measure	To agree for pilot	Marketplace lead
Conversation activation	To measure	To set after chat eligibility is defined	Product owner
Repeat usage	To measure	To set after pilot duration is chosen	Business owner
Support burden	To measure	Capacity limit to be agreed	Operations owner

Data quality checks

- Reconcile task/application counts against authoritative records weekly.
- Check duplicate events and client retries before calculating rates.
- Exclude test accounts and internal seed data consistently.
- Verify state-transition timestamps are monotonic and timezone-normalized.
- Document late-arriving events and dashboard refresh time.
- Review event payloads before launch to prevent accidental collection of sensitive content.

Review cadence and decisions

Review the dashboard weekly during the pilot. Choose one primary bottleneck, assign an owner, and document the change being tested. Do not treat correlation as causation. After the pilot, decide whether to continue the segment, change onboarding, adjust task quality controls, test pricing, or stop.

Open definitions

Pilot length; eligible active-user definition; qualified-application rubric; match definition; task completion signal; retention windows; event retention; analytics tool/source; metric owner; and the target thresholds needed for go/no-go decisions.
